

CS396 Software Design Principles and Practices

Project: Milestone 2 Report

Project Progress Evaluation

(Instruction: Please evaluate your progress against the Project Planning you proposed in Milestone 1. Adjust the plan if needed. If you haven't, you may want to plan your action items to the day or even hours to make sure you have a successful completion.)

In our project plan, we aimed to produce the original design PUML and the new design for the first 4 use cases. This week, we were only able to produce the original design PUML (please find below).

By 6/4, we will finish all 6 use cases in the new PUML design and refactor the codebase by the deadline. Although the original plan stated that we should progress use case by use case, we have discovered that it is not applicable to judge our progress as such. For example, UC 1 is the base UC where drones are generated and updated as the simulation progresses. Our plan for updating the new functionality is to create a mission control class that reads from the csv files and sends information to the Drone Manager. However, this update impacts the rest of the use cases, as all of them would rely on the new Mission Control instead of Drone Manager for position information. Therefore, we cannot judge progress using use cases.

Instead, we will progress by fixing sections of the system at a time, and patch them all together in a comprehensive report that details the use case:

1. Creating a mission control class that handles reading the CSV files and updating key information to the rest of the system
2. Creating a Cube class that connects with the "InvertSaddleCubePrefab" and "DefaultSaddleCubePrefab" GameObjects. This class will handle all business logic related to the cube generation, relieve Drone Manager of these tasks and promoting better cohesion.

Beyond these two updates, we will consider the below:

1. Separating the arrow creation and update logic from the Drone Manager, as similar functions exist in ArrowDrawer. Although these methods are used differently, arrow creation and updating are not necessarily related to managing drones and can be removed from Drone Manager.
2. Implementing an algorithm system for updating the camera position in AutoCameraControl. To promote better cohesion, we can create a separate class that AutoCam can rely on in order to streamline the adding and subtracting more cleanly.

These updates will comprehensively update all 6 UCs.

Do You Have Any Questions About the Grading Rubrics?

(Instructions: please answer no or yes with your questions.)

No.

Do You Have Any Other Questions?

(Instructions: please answer no or yes with your questions.)

No.
